ABSTRACT

Since it began, shrimp mariculture research in Texas has been supported by The Texas A&M University System and the Texas A&M Sea Grant College Program. This paper summarizes the development of shrimp mariculture in Texas and the research objectives of shrimp culture facilities at Angleton and Corpus Christi, Texas. In addition, it presents weekly growth and water quality data from research at the facilities between 1969 and 1978.

ACKNOWLEDGEMENTS

The authors thank the personnel of the mariculture facilities at Angleton and Corpus Christi for their patience and hard work in preparing the manuscript and the data; Patti and Vikki Johns for helping with the preparation of data; Elsie Kettunen for her assistance in writing the computer program that tabulated the data; and Ruth Spear for her patience in typing the manuscript.

INTRODUCTION

Recently, much attention has been given to the development of a shrimp mariculture industry in the United States. Shrimp is expensive, and consumer demand for shrimp and shrimp products is high and constant. Half the shrimp consumed in the country is imported. Costs of operating shrimp trawlers have increased steadily as a result of rising fuel prices and interest rates (Fisher, 1975; Brown, 1977). Texas, with its long growing season and abundance of suitable land, has been in the forefront of shrimp mariculture research, most of which has been supported by the Sea Grant College Program at Texas A&M University. Sea Grant has provided funds for research, technical reports and public education.

Shrimp mariculture research in the United States began in 1963 when Dr. Motosaku Fujinaga, Japan's "father of shrimp culture," visited the National Marine Fisheries Service (NMFS) laboratory at Galveston, Texas. Using techniques developed by Japanese scientists, NMFS researchers there spawned and reared larvae of two shrimp species native to the Gulf of Mexico, Penaeus setiferus and Penaeus aztecus.

This early work stimulated industry to investigate the commercial potential of mariculture. Dow Chemical, Ralston Purina, Armour, Florida Power and Light, and Central Power and Light companies became deeply involved in early shrimp farming ventures. In 1967 Marifarms Inc. was established in Florida. Soon thereafter Sea Farms Inc. of Key West began producing penaeid shrimp and fish (Hanson and Goodwin, 1977). In the late 1960's and early 1970's several other companies began shrimp farming.

The Coca-Cola Company, Weyerhauser Company and Union Carbide (Anonymous, 1978), in cooperation with government agencies and universities, became involved in research and development of both engineering and biological aspects of shrimp mariculture. Work has also been done at the University of Miami's Institute of Marine Science and at the Ocean Springs Laboratory in Mississippi.

In Texas, NMFS at Galveston and Texas A&M in Brazoria County and Corpus Christi, in cooperation with Ralston Purina, have made important advances in shrimp mariculture. This report provides a brief history of shrimp mariculture research at Texas A&M facilities near Angleton and Corpus Christi and presents growth and water quality data from experiments performed there between 1969 and 1978.

RESEARCH AT THE TEXAS A&M SYSTEM

Since the late 1960's researchers of The Texas A&M University System, with support from Sea Grant, other state and federal agencies and industry, have made significant technological progress toward commercial production of shrimp (Adams et al., 1980; Hanson, 1979; and Goodwin, 1977). Production experiments are performed at mariculture facilities near Angleton and Corpus Christi. Studies have used native Gulf of Mexico shrimp (Penaeus aztecus, P. duorarum and P. setiferus) and several Central American shrimp (notably P. stylirostris and P. vannamei) (Brown, 1977). Early studies showed that P. setiferus, P. stylirostris and P. vannamei are superior in growth, maturation and ease of culture (Parker, 1974a,b, 1978; Parker and Holcomb, 1973).

Sea Grant has supported many aspects of shrimp mariculture research. Through studies of nutrition and growth a low-cost feed has been developed that promotes optimum growth of shrimp in captivity (Parker and Holcomb, 1973; Gould et al., 1973; Parker, 1975; Rubright et al., 1981).

Disease and parasitism can drastically decrease production in culture facilities. Research in bacteriology, virology, parasitology and immunology has received high priority because efficient shrimp production depends on diagnosis, treatment and prevention of health problems (Lewis, 1976, 1981; Johnson, 1974a, b, c, d, 1975a, b; 1976a, b; Johnson et al., 1974).

Independence from wild shrimp populations is necessary before

shrimp mariculture can become a successful industry. Therefore, achieving all stages of the life cycle -- spawning, maturation, reproduction -- in captivity has been another thrust of the program. Penaeus setiferus, P. vannamei and P. stylirostris have spawned in the maturation/reproduction facility near Corpus Christi (Brown et al., 1979, 1980; Middleditch et al., 1979, 1980; Lawrence et al., 1979, 1980; Chamberlain et al., 1980; Chamberlain and Lawrence, 1981). Cryogenic storage is being investigated as a means of transporting the nauplius larvae of shrimp and Artemia (brine shrimp), the food for the mysis larval stages, to remote facilities (Baust and Lawrence, 1979, 1980a, b).

Economists have incorporated shrimp production, environmental and economic data obtained from these studies into a computerized bioeconomic model. The model predicts which pond conditions result in highest shrimp production and profits, and management strategies may be adjusted accordingly (Adams et al., 1980; Hanson, 1979; Griffin et al., 1981; Johns et al., 1981).

THE ANGLETON MARICULTURE FACILITY

In 1968 Sea Grant provided funds to the Texas Agricultural Extension Service to support mariculture research on the Texas Coast, and Texaco provided land on the West Galveston Bay shore near Angleton in Brazoria County (Parker, 1969). Pond construction began in February 1969 with equipment and personnel from the Brazoria County Commissioner's Court and the Brazoria County Mosquito Control District (Parker, 1969). Early facilities included 10 one-half-acre (0.2-ha) ponds and three natural marsh ponds from 1.0 to 2.5 acres (0.4-1.0 ha).

In 1969 and 1970 research focused on comparison of pelleted supplemental shrimp feeds of low and high protein content (Parker and Holcomb, 1973). It soon was obvious that the production capacity of P. setiferus was superior to that of P. aztecus and P. duorarum (Holcomb and Parker, 1973). During 1969-1971 criteria were established for site selection and preliminary pond design and management, and an efficient harvest system was developed (Holcomb and Parker, 1973). Ten ponds were added in 1971, bringing the number of ponds to 20. Inorganic fertilizer added to the system enhanced shrimp production, and a fertilizing rate was established. Also in 1971 it was established that extruded flake feeds were superior to pellet feeds. Shrimp fed extruded flake feeds of two different protein levels (35 and 45 percent) showed no difference in growth rates.

In 1972 two different fertilization rates were compared, as were extruded flake feeds of 25 percent and 35 percent protein. Again, protein content made no difference in shrimp growth rates.

In 1972 a raceway was incorporated into the pond system to allow exchange of water between ponds.

In 1973 it was determined that the production of two non-native shrimp species (P. vannamei and P. stylirostris) was comparable, if not superior, to that of the Gulf species.

During 1974 two five-acre (2.0-ha) ponds, were constructed with funding from Booth Fisheries to evaluate production and costs of production of shrimp fed natural food and supplemental rations (Parker, 1975). Extruded flake feed containing only 20 percent protein produced shrimp growth rates as high as the feeds tested in 1971 and 1972. Using the low-protein feed further lowers the cost of shrimp production.

Sourcing -- collecting gravid (egg-bearing) females in the wild and taking them to the laboratory to spawn (Bardach et al., 1972) --- was emphasized between 1975 and 1977. Spawning sites of P. setiferus were found near Freeport and Port Aransas, Texas. It was determined that P. setiferus spawns from May through August and that they mate at dusk (Parker, 1978). Paralleling the sourcing program, a hatchery program was developed at the NMFS hatchery at Galveston. More than 300 mated females were delivered to the hatchery and spawned 40 million eggs. From these eggs, 30 million nauplius larvae and 5.5 million post-larvae were produced.

Since 1978 research has focused on pond ecology. Understanding relationships between pond dynamics and shrimp production is a key to shrimp mariculture's success. At present, the research focuses on changes that occur in the pond as a result of management practices, specifically the effects of inorganic fertilizer, supplemental feeding, aeration and water exchange on water quality and populations of phytoplankton, zooplankton, benthos and shrimp. The cast net sampling technique for estimating shrimp populations is also being perfected.

THE CORPUS CHRISTI MARICULTURE FACILITY

In 1972 Texas A&M, with the cooperation of the Central Power and Light Company (CP&L), constructed a unique three-level shrimp production facility adjacent to CP&L's Barney M. Davis Power Station at Flour Bluff near Corpus Christi (Colunga, 1974). The three-pond series includes a one-eighth-acre (0.05-ha) nursery pond, a one-quarter-acre (0.1-ha) intermediate pond and a one-half-acre (0.2-ha) grow-out pond. As the shrimp grow they pass through the series of ponds, using each to its capacity. The three-pond system was tested with P. vannamei in 1973. Two record harvests yielded a total of 4,064 lb/acre of 61-count whole shrimp and 4,696 lb/acre of 62-count whole shrimp (Conte and Parker, 1974). Theoretically, the system could produce three crops per year with an extrapolated annual yield of more than 8,000 lbs per acre.

In 1974 18 one-quarter-acre (0.1-ha) ponds were constructed that can be filled with water from either the Laguna Madre or the power plant's cooling lake (Chamberlain et al., 1980). In 1974 work began on evaluation of heated effluent for overwintering broodstock of P. vannamei, P. stylirostris and P. setiferus for maturation (Conte, 1975). This work was resumed in 1978 (Conte et al., 1977).

During 1975 experiments tested the production of P. vannamei, P. stylirostris and P. setiferus at different stocking densities.

Early entry studies (stocking nauplii directly and omitting the hatchery stage) were made in 1976 for P. setiferus. No production data

were obtained that year.

In 1977 six ponds were stocked with 80,000 P. setiferus with funding from a Southeast Asia (S.E.A.) grant. Shrimp in these ponds grew slowly, and mean salinity readings were high. Flow rate studies using P. vannamei were performed in 1978, and again high salinities caused low growth rates.

In 1978 routine population estimates were made during the grow-out season to obtain information on shrimp population dynamics in ponds. Two sampling techniques were used, the Peterson mark-recapture method, in which shrimp were marked by removal of the end of the right uropod, and a stratified random sampling method using cast net catches (Hutchins et al., 1980).

At present, the thrusts of research at the Corpus Christi facility are shrimp maturation/reproduction and cryogenics.

POND PRODUCTION DATA

Pond production data are tabulated in Appendix A for the Angleton facility, 1969-1978, and in Appendix B for the Corpus Christi facility, 1973-1975 and 1977-1978. Tables are arranged by year, and headings include the following information: shrimp species, pond number, date of stocking, stocking density, date of harvest, harvest weight and percent survival. Each table lists the following data: date, mean weight (g), mean length (mm), mean temperature ($^{\circ}$ C), mean salinity (ppt) and dissolved oxygen (ppm). Asterisks denote that no data were available. The date is the weekly date on which mean length and weight were measured during the grow-out season. Water quality data are averages of daily readings for each week of growth data.

Data were stored and assimilated on the AMDAHL/370 computer system at Texas A&M, College Station, Appendix C gives the FORTRAN program used to set up the tables in Appendices A and B.
